# Digital logic

CS 211: Computer Architecture

# Applying DeMorgan's Laws to gates

$$\overline{X} + \overline{Y} = \overline{XY}$$

$$XY = \overline{\overline{X} + \overline{Y}}$$

$$\overline{X}\overline{Y} = \overline{X + Y}$$

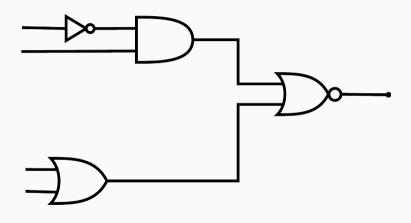

$$\exists \bigcirc \longleftarrow \Rightarrow \bigcirc \frown$$

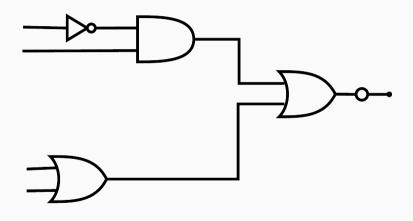

$$X + Y = \overline{\overline{X}}\overline{Y}$$

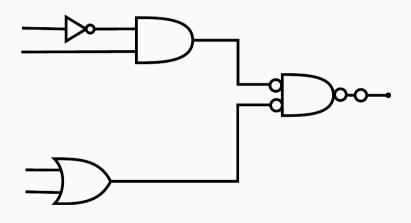

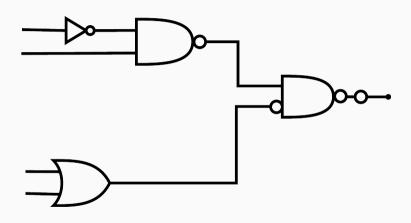

To convert a circuit to all NAND gates, use the previous gate conversions, plus the NOT conversion below. Start from the output and work backwards towards the inputs.

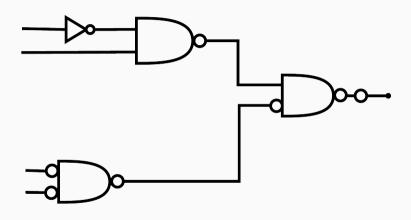

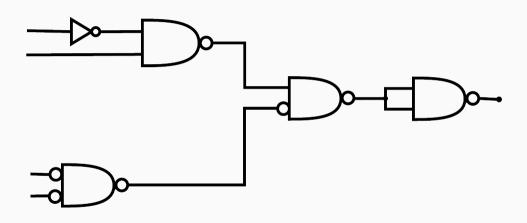

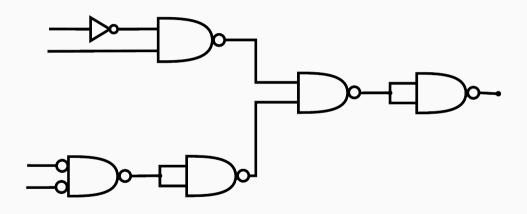

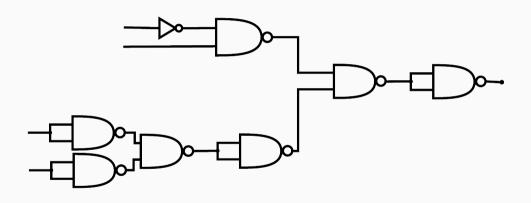

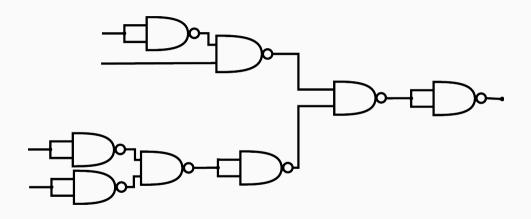

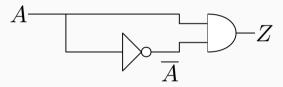

# Timing

In this circuit, what value should Z have?

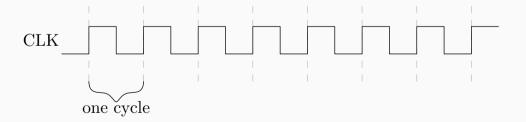

# Timing

#### **Timing**

One way to deal with this is with synchronous circuits, that use a clock signal to know when to update.

1 Hz = 1 cycle / second

1 GHz = 1 billion cycles / second

# Adding two bits

We can add two single bits:

| Α | В | S |
|---|---|---|
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 0 |
|   |   |   |

### Adding two bits

Let's also output the carry bit:

| Α | В | S | C |
|---|---|---|---|
| 0 | 0 | 0 | 0 |
| 0 | 1 | 1 | 0 |
| 1 | 0 | 1 | 0 |
| 1 | 1 | 0 | 1 |
|   |   |   |   |

# Adding two 4-bit numbers

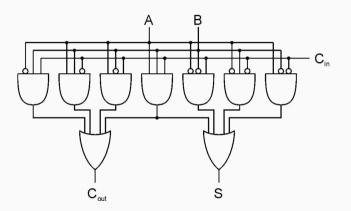

Let's add 1010 and 0011:

# Adding two bits

Let's also add an *input* carry bit:

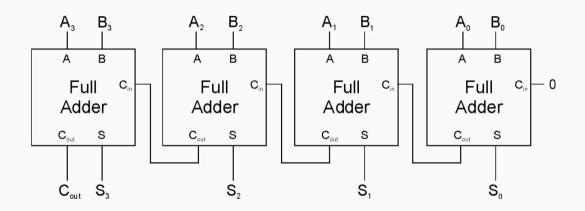

| Α | В | $C_{in}$ | S | $C_{out}$ |
|---|---|----------|---|-----------|
| 0 | 0 | 0        | 0 | 0         |
| 0 | 0 | 1        | 1 | 0         |
| 0 | 1 | 0        | 1 | 0         |
| 0 | 1 | 1        | 0 | 1         |
| 1 | 0 | 0        | 1 | 0         |
| 1 | 0 | 1        | 0 | 1         |
| 1 | 1 | 0        | 0 | 1         |
| 1 | 1 | 1        | 1 | 1         |

# Adding two bits

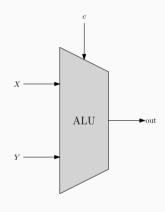

| А | В | $C_{in}$ | S | $C_out$ |
|---|---|----------|---|---------|
| 0 | 0 | 0        | 0 | 0       |
| 0 | 0 | 1        | 1 | 0       |
| 0 | 1 | 0        | 1 | 0       |
| 0 | 1 | 1        | 0 | 1       |
| 1 | 0 | 0        | 1 | 0       |
| 1 | 0 | 1        | 0 | 1       |
| 1 | 1 | 0        | 0 | 1       |
| 1 | 1 | 1        | 1 | 1       |

### Adding two 4-bit numbers

# Arithmetic logic unit (ALU)

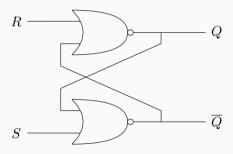

| out   |  |
|-------|--|
| X + Y |  |
| X - Y |  |
| X * Y |  |
| X/Y   |  |
|       |  |

#### Sequential circuits

So far all circuits have been combinational, functions from input to output.

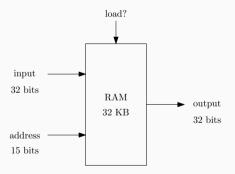

Sequential circuits also have a way to preserve state.

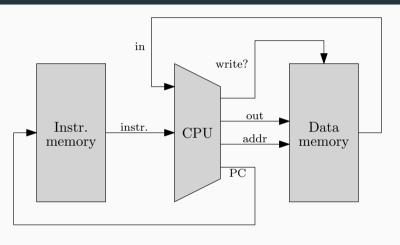

#### Memory

Once we have a circuit that can store one bit:

- · combine 32 of them to make a 32-bit register
- · combine registers to make a RAM module
