211: Computer Architecture C programming, part 1

Topic:

C Programming

Introduction to C

TAs will cover C in more details in sections

Will also help you with machine/compilation logistics

Learning C

- Is no big deal; you already know Java
- Start by coding and testing small programs
- Learn how to use a debugger!

Why Learn C?

You are learning to be a computer scientist

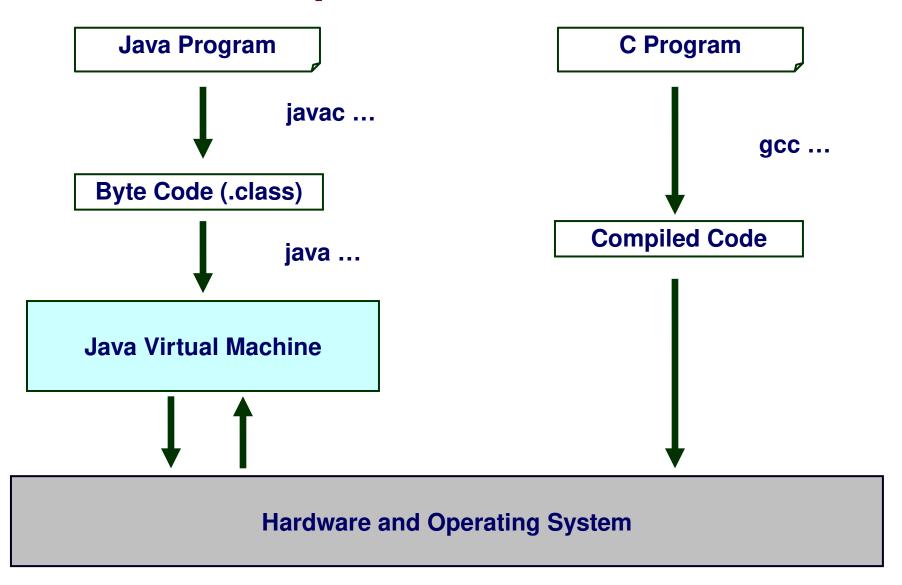

- Languages are just tools
- Choose tool appropriate to the task

Current task: learning computer architecture and how programs written in high-level language runs on computers

C closer to machine so easier to see mapping

It's fun

Comparison with Java

Anatomy of a C Program

```
include files
#include <stdio.h>
#include <stdlib.h>
                                                declaration of global
                                                     variables
char cMessage[] = "Hello\n";
/* Execution will start here */
                                                     comment
int main (int argc, char **argv)
                                               one or more function;
    int i, count; -
                                                each program starts
                                                execution at "main"
    count = atoi(argv[1]);
    for (i = 0; i < count; i++) {
         printf("Hello %d\n", i);
                                                declaration of local
                                                     variables
                               code implementing
                                    function
```

Comments

Begins with /* and ends with */

Can span multiple lines.

Cannot have a comment within a comment or string

Example:

"my/*don't print this*/string"

would be printed as: my/*don't print this*/string

Comments are critical

How much and where is an art

Variable Declarations

Variables are used as names for data items

Each variable has a type, which tells the compiler how the data is to be interpreted (and how much space it needs, etc.)

```
int counter;
int startPoint;
```

Variables can be global or local

global: declare outside scope of any function accessible from anywhere

local: declare inside scope of a function accessible only from inside of the function

Basic Data Types

Keyword	Data Type	Examples
char	individual characters	'a', 'b', '\t', '\n'
int	integers	-15, 0, 35
float	real numbers	-23.6, 0, 4.56
double	real numbers with double precision	-23.6, 0, 4.56

Modifiers

- short, long: control size/range of numbers
- signed, unsigned: include negative numbers or not

Arithmetic Operators

```
Symbol Operation Usage Assoc

* multiply x * y l-to-r

/ divide x / y l-to-r

% modulo x % y l-to-r

+ addition x + y l-to-r

- subtract x - y l-to-r
```

Rule of thumb: remember only a few precedence rules Use () for everything else

^{* / %} have higher precedence than + -

Special Operators: ++ and --

Changes value of variable before (or after) its value is used in an expression

Symbol	Operation	Usage
++	postincrement	X++
	postdecrement	X
++	preincrement	++X
	predecrement	X

Pre: Increment/decrement variable before using its value

Post: Increment/decrement variable after using its value

Be careful when using these operators!

Relational Operators

```
Symbol
           Operation
                                  Usage
           greater than
                                  X > Y
   >
           greater than or equal x \ge y
   >=
           less than
                                  X < Y
   <
           less than or equal
                                  X \le y
   <=
           equal
                                  X == y
   ==
   !=
           not equal
                                  x != y
```

Result is 1 (TRUE) or 0 (FALSE)

Don't confuse equality (==) with assignment (=)

Logic Operators

Symbol	Operation	Usage	Assoc
!	logical NOT	!x	r-to-l
&&	logical AND	x && y	l-to-r
	logical OR	x y	l-to-r

Treats entire variable (or value) as TRUE (non-zero) or FALSE (zero) Result is 1 (TRUE) or 0 (FALSE)

Bit Operators

Symbol	Operation	Usage	Assoc
~	complement	~X	r-to-l
&	bit AND	x & y	l-to-r
	bit OR	x y	l-to-r

Operate on bits of variables or constants

For example:

- **■** ~0101 = 1010
- **1** 0101 & 1010 = 0000
- **1** 0101 | 1010 = 1111

Expressions and Assignments

Expression = "a computation" with a result

- \blacksquare (X + Y) * Z
- Be careful of type conversion!

```
int x, z; float y;
```

the result of the expression (x + y) * z will have what type?

Assignment

- X = (X + y) * Z;
- The assignment statement itself is an expression and has a value. In this case, it's the value assigned to x.

Control Statements

Conditional

- if else
- switch

Iteration (loops)

- while
- for
- do while

Specialized "go-to"

- break
- continue

The if Statement

```
if (expression-1) {statements-1}
else if (expression-2) {statements-2}
else if (expression-n-1) {statements-n-1}|
else {statements-n}
```

Evaluates expressions until find one with non-zero result

executes corresponding statements

If all expressions evaluate to zero, executes statements for "else" branch

The switch Statement

```
switch(expression) {
  case const-1: statements-1;
  case const-2: statements-2;
  default: statements-n;
}
```

Evaluates expression; results must be integer

Finds 1st "case" with matching contant

- Executes corresponding statements
- Continue executing until encounter a break or end of switch statement

"default" always matches

The switch Statement (Example)

```
int fork;
switch(fork) {
     case 1:
         printf("take left'');
     case 2:
         printf("take right");
         break;
     case 3:
         printf("make U turn");
         break;
     default:
         printf("go straight");
```

Loops

Statement	Repeats set of statements
while (expression) {}	zero or more times, while expression != 0, compute expression before each iteration
do {} while (expression)	one or more times, while expression != 0 compute expression after each iteration
for (start-expression; cond-expression; update-expression) {}	zero or more times while cond-expression != 0 compute start-expression before 1st iteration compute update-expression after each iteration

Specialized Go-to's

break

- Force immediate exit from switch or loop
- Go-to statement immediately following switch/loop

continue

- Skip the rest of the computation in the current iteration of a loop
- Go-to evaluation of conditional expression for execution of next iteration

Specialized Go-to's (Example)

What does the following piece of code do?

```
int index = 0;
int sum = 0;
while ((index >= 0) && (index <= 20))
{
   index += 1;
   if (index == 11) break;
   if ((index % 2) == 1) continue;
   sum = sum + index;
}</pre>
```

Functions

Similar to Java methods

Components:

- Name
- Return type
 - void if no return value
- Parameters
 - pass-by-value
- Body
 - Statements to be executed
 - return forces exits from function and resumes execution at statement immediately after function call

```
int factorial(int n)
{
    int i;
    int result = 1;
    for (i = 1; i <= n; i++)
        result *= i;
    return result;
}</pre>
```

Function Calls

Function call as part of an expression

- x + factorial(y)
- Arguments evaluated before function call
 - Multiple arguments: no defined order or evaluation
- Returned value is used to compute expression
- Cannot have a void return type

Function call as a statement

- factorial(y);
- Can have a void return type
- Returned value is discarded (if there is one)

Function Prototypes

Can declare functions without specifying implementation

- int factorial(int)
 - Can specify parameter names but don't have to
 - This is called a function signature

Declarations allow functions to be "used" without having the implementation until link time (we'll talk about linking later)

- Separate compilation
 - Functions implemented in different files
 - Functions in binary libraries
- Signatures are often given in header files
 - E.g., stdio.h gives the signatures for standard I/O functions

Input and Output

Variety of I/O functions in C Standard Library

```
#include <stdio.h>
printf("%d\n", counter);
```

- String contains characters to print and formatting directives for variables
- This call says to print the variable counter as a decimal integer, followed by a linefeed (\n)

```
scanf("%d", &startPoint);
```

- String contains formatting directives for parsing input
- This call says to read a decimal integer and assign it to the variable startPoint. (Don't worry about the & yet.)

Memory

C's memory model matches the underlying (virtual) memory system

Array of addressable bytes

1	
2	
3	
4	
5	
6	
7	
8	
9	
10	
11	
12	
13	

Memory

C's memory model matches the underlying (virtual) memory system

int x

Array of addressable bytes

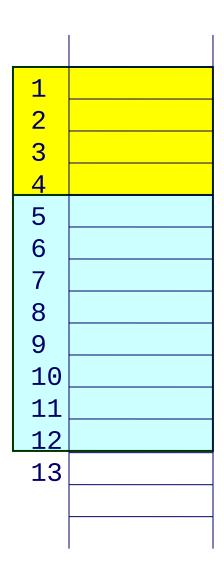

Variables are simply names for contiguous sequences of bytes

double y

Number of bytes given by type of variable

Compiler translates names to addresses

- Typically maps to smallest address
- Will discuss in more detail later

Pointers

A pointer is just an address

Can have variables of type pointer

- Hold addresses as values
- Used for indirection

When declaring a pointer variable, need to declare the type of the data item the pointer will point to

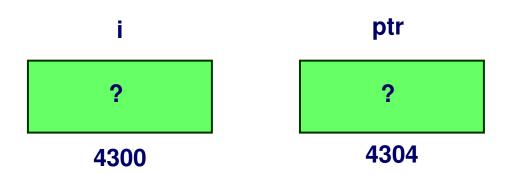

int *p; /* p will point to a int data item */

Pointer operators

- De-reference: *
 - *p gives the value stored at the address pointed to by p
- Address: &
 - &v gives the address of the variable v

```
int i;
int *ptr;

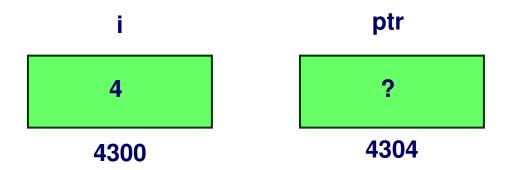

i = 4;
ptr = &i;
*ptr = *ptr + 1;
```

```
int i;
int *ptr;

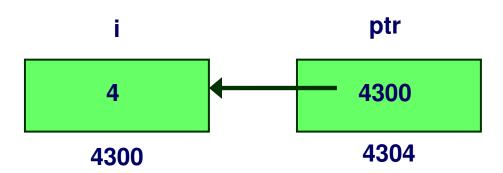

i = 4;

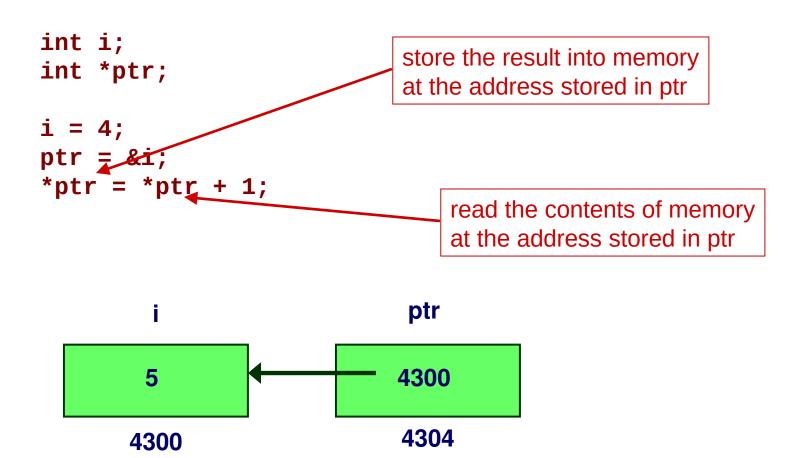

ptr = &i;
*ptr = *ptr + 1;
store the value 4 into the memory location
associated with i
```

```
int i;
int *ptr;

i = 4;
ptr = &i;
*ptr = *ptr + 1;
store the address of i into the
memory location associated with ptr
```

Example Use of Pointers

What does the following code produce? Why?

```
void Swap(int firstVal, int secondVal)
{
    int tempVal = firstVal;
    firstVal = secondVal;
    secondVal = tempVal;
}
...
int fv = 6, sv = 10;
Swap(fv, sv);
printf("Values: (%d, %d)\n", fv, sv);
```

Parameter Pass-by-Reference

Now what does the code produce? Why?

```
void Swap(int *firstVal, int *secondVal)
{
    int tempVal = *firstVal;
    *firstVal = *secondVal;
    *secondVal = tempVal;
}
...
int fv = 6, sv = 10;
Swap(&fv, &sv);
printf("Values: (%d, %d)\n", fv, sv);
```

Null Pointer

Sometimes we want a pointer that points to nothing

In other words, we declare a pointer, but we're not ready to actually point to something yet

```
int *p;
p = NULL; /* p is a null pointer */
```

NULL is a predefined constant that contains a value that a non-null pointer should never hold

Often, NULL = 0, because address 0 is not a legal address for most programs on most platforms
